

Hair Loss Treatment: PRP Therapy

The dermatologists at Scarsdale Medical Group are offering an innovative treatment method to restore hair growth. Platelet Rich Plasma (PRP) therapy is a sophisticated, non-surgical solution for male and female patients suffering from alopecia, or hair loss.

What is PRP Therapy?

Platelet rich plasma therapy is derived by extracting blood and using a centrifuge to spin and separate the platelets and plasma. PRP contains essential proteins and growth factors from your own blood that are injected into the scalp using a very small needle that stimulates the growth and rejuvenation of new cells while reducing hair loss. Hair density and thickness are improved, and both men and women can benefit from treatments.

What are the advantages of PRP Therapy?

This type of treatment is safe, non-invasive, has minimal to no side effects, requires no 'downtime' and patients can resume normal activities immediately after treatment. Patients will not undergo any surgery, require any bandages or have scars post-treatment.

Who is a good candidate for PRP Therapy?

Patients with early stage hair loss experience the most promising results. PRP promotes hair growth when follicles are still present. Those with extreme hair loss or non-existent follicles are generally not good candidates for this treatment.

It's best to first consult one of our dermatologists to determine if PRP therapy is right for you.

How long until I see results?

Each patient is different but typically hair growth will begin approximately three months after treatment. We recommend one treatment per month for the first three to four months. Then, maintenance treatments a few times per year are generally recommended. Your doctor will determine what's best for you.
